

Claims

1. A computer implemented method for automatic software tuning comprising the steps of:
 - 5 calculating (410) at least one threshold value for at least one parameter (P1) influencing the performance of a software application (200) with regards to a specific task;
 - comparing (430) the at least one threshold value to
 - 10 at least one corresponding current value; and
 - selecting (440) an algorithm (A1) from a plurality of algorithms (A1 to AN) for performing the task in accordance with the result of the comparing step (430).
- 15 2. Method of claim 1 comprising the further steps of:
 - measuring (450) the performance of the selected algorithm (A1);
 - checking (460) whether the measured performance
 - 20 complies with the at least one threshold value; and
 - recalculating (470) the at least one threshold value in case of non-compliance.
- 25 3. Method of any one of the previous claims, where the at least one threshold value separates the value range of the parameter (P1) into at least two intervals of a first dimension.

4. Method of claim 3, wherein the selecting step (440) selects the algorithm (A1) that is assigned to the interval that includes the corresponding current value of the first dimension.
- 5
5. Method of claim 3, where at least one further threshold value separates the value range of a further parameter into at least two intervals of a second dimension.
- 10
6. Method of claim 5, wherein the selecting step (440) selects the algorithm (A1) that is assigned to the intersection of the interval of the first dimension that includes the corresponding current parameter value of the first dimension and the interval of the second dimension that includes the corresponding current parameter value of the second dimension.
- 15
7. Method of any one of the claims 3 to 6, wherein each threshold value corresponds to a break-even point where two neighbouring algorithms have the same performance with respect to the corresponding dimension.
- 20
8. A computer program product for automatic software tuning comprising a plurality of instructions that when loaded into a memory of a computer system (990) cause at least one processor of the computer system (900) to execute the steps of any one of the claims 1 to 7.
- 25
9. Information carrier comprising the computer program product of claim 8.
- 30
- 35

10. A computer program product for dynamically selecting a data retriever implementation for retrieving data from a data storage system (902) in response to a Boolean expression (500) comprising:
- 5 a result counter (102) to determine a number of hits in response to the Boolean expression;
- a threshold evaluator (103) to compare the number of hits with a threshold value of a first dimension and to compare the complexity of the Boolean expression with a further threshold value of a second dimension;
- 10 a first data retriever (111) to retrieve the data in case the number of hits is below the threshold value of the first dimension and the complexity of the Boolean expression is above the further threshold value of the second dimension;
- 15 a second data retriever (112) to retrieve the data in case the number of hits is above the threshold value of the first dimension and the complexity of the Boolean expression is above the further threshold value of the second dimension;
- 20 a third data retriever (113) to retrieve the data in case the number of hits is below the threshold value of the first dimension and the complexity of the Boolean expression is below the further threshold value of the second dimension; and
- 25 a fourth data retriever (114) to retrieve the data in case the number of hits is above the threshold value of the first dimension and the complexity of the Boolean expression is below the further threshold value of the second dimension.
- 30
- 35

11. The computer program product of claim 10, further comprising:
- a retrieval time measuring component (104) to
5 measure the time that is consumed by a selected
 data retriever (111, 112, 113, 114) for various
 numbers of hits; and
 - a threshold calculator (105) to dynamically
10 determine the threshold value and the further
 threshold value on the basis of the results of
 the retrieval time measuring component (104)
 and to feed back the determined threshold
 values into the threshold evaluator (103).
- 15 12. The computer program product according to claim 11,
 where the first data retriever (111) is implemented
 by using a general data retrieval algorithm using
 result flag instances.
- 20 13. The computer program product according to claim 11
 or 12, where the second data retriever (112) is
 implemented by using a general data retrieval
 algorithm using bit maps.
- 25 14. The computer program product according to any one
 of the claims 11 to 13, where the third data
 retriever (113) is implemented by using a lean AND
 data retrieval algorithm using result flag
 instances.
- 30 15. The computer program product according to any one
 of the claims 11 to 14, where the forth data
 retriever (114) is implemented by using a lean AND
 data retrieval algorithm using bit maps.

16. A computer system (990) comprising:
a memory to store a computer program product
5 according to any one of the claims 10 to 15;
and
at least one processor to execute instructions of
the computer program product according to any
one of the claims 10 to 15.
- 10 17. A computer system (990) for running a software
application (200) comprising:
variables (210) for storing at least one threshold
value for at least one parameter (P1)
15 influencing the performance of the software
application (200) with regards to a specific
task; and
a threshold evaluator (220) for comparing (430) the
at least one threshold value to at least one
20 corresponding current value allowing the
software application (200) to select (440) an
algorithm (A1) from a plurality of algorithms
(A1 to AN) for performing the task in
accordance with the result of comparison.
- 25 18. The computer system (990) of claim 17, further
comprising:
a threshold calculator (230) for recalculating
(470) the at least one threshold value in case
30 the actual performance of the selected
algorithm (A1) is non-compliant with the at
least one threshold value.

19. The computer system (990) of claim 17 or 18, where
the at least one threshold value separates the
5 value range of the parameter (P1) into at least two
intervals of a first dimension.
20. The computer system (990) of claim 19, wherein the
selected algorithm (A1) is assigned to the interval
10 that includes the corresponding current value of
the first dimension.
21. The computer system (990) of claim 19, where at
least one further threshold value separates the
15 value range of a further parameter into at least
two intervals of a second dimension.
22. The computer system (990) of claim 21, wherein the
selected algorithm (A1) is assigned to the
20 intersection of the interval of the first dimension
that that includes the corresponding current
parameter value of the first dimension and the
interval of the second dimension that that includes
the corresponding current parameter value of the
25 second dimension.
23. The computer system (990) of any one of the claims
19 to 22, wherein each threshold value corresponds
to a break-even point where two neighbouring
30 algorithms have the same performance with respect
to the corresponding dimension.
